

XML

- eXtended Markup Language
- Initial goal to represent data in electronic form
- Device & System independent
- Meta-Language
 - Markup language
 - Less complex than SGML
 - Powerful
 - May be parsed by SGML parsers with special extensions
- Base for almost all new data representation languages

Motivation for XML

- Problems with HTML
 - Intended for visualization
 - Mixes content and style (layout)
 - Difficult to automatically transform
- - Describes information in a document
 - No visualization
 - Says what a document means

More HTML problems

- HTML is static
 - Not extensible
 - Set of elements is fixed
- No Semantic information
- Not designed for device-independence
 - Different on desktop browsers, PDAs, ...
- Layouting features rather weak
 - CSS

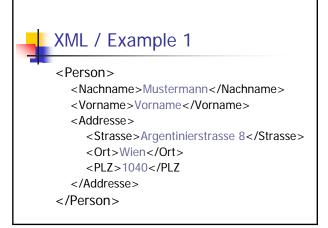

XML / 1

- Meta-language
 - Defining new languages

 - Example: XHTML
 Redesigned HTML, conforms to XML
- Application of XML
- Introducing such a language
- Supports structure
 - Through structure of tags
- Supports semantics

 - Meaning of tags<Person>Mustermann</Person> vs. "Mustermann"
 - Important for automation

XML / Example 2

- Whitespaces don't matter:
- <Person>
- <Nachname>Mustermann</Nachname>
 <Vorname>Vorname</Vorname><Add
 resse <Strasse>Argentinierstrasse
 8</Strasse><Ort>Wien</Ort><PLZ>1
 040</PLZ</Addresse></Person>

Goals for XML

- Easy to read and process
 - More important: easy for machines
- Separation of layout and content
- Typed documents
- Compatible with SGML
- Unicode

Application Areas / 1

- World Wide Web
 - XML sent to client, rendering on client
 - XML rendered on server, HTML sent to client
- Separation of layout and content
- Automatic generation of navigational structures

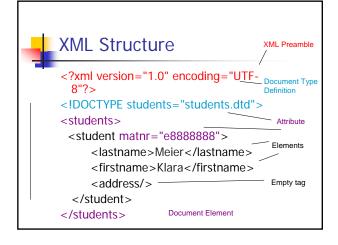

Application Areas / 2

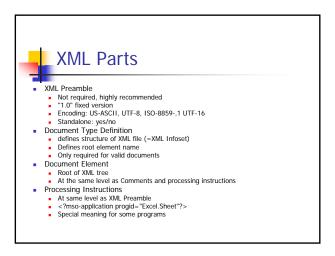

- Data Exchange / Interoperability
 - SOAP (later)
 - WebDAV (later)
 - BPEL (Business Process Execution Language)
- XML to enhance databases
 - Most commercial DBs support XML as result-set
 - Next generation:
 - Support XML as first class datatype
 - Supports querying within XML structures
- XML as structured databases
 - Eg. Apache Xindice

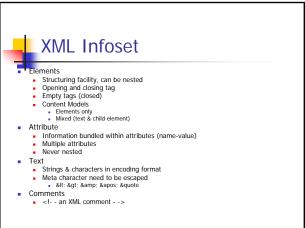

Application Areas / 3

- Domain Specific Languages (DSL)
 - MathML, SVG, MusicML, RDF, XMI
 - Ant build.xml
 - .NET Configuration files

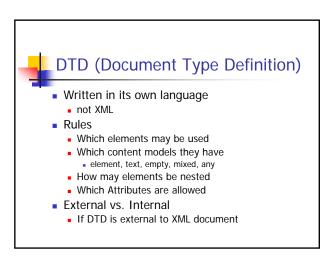

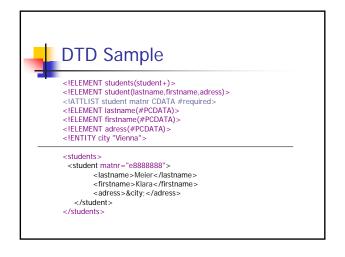

DTD / Schema

- Valid XML documents
 - Well-Formed & conforms to rules in DTD or Schema
 - An application may required a certain structure
- Meta-Information about documents
 - DTD / Schema describe a set of documents (that conform to the rules)
- Parsers and representation classes can be generated from DTDs / Schemas

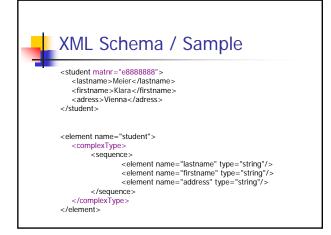

XML Schema

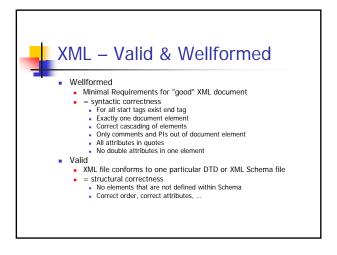

- Successor of DTD
- Formulated in XML
- Context-free regular grammar for defining arbitrary XML structures
- Better support for versions of elements and attributes
 - More restrictions, more checks
- No support for Entities!
 - Entities in DTDs are like macros

XML Namespaces

- Avoid name clashes when documents are merged or interchanged
 - Unique naming
 - <Address> element of two different origins do not have necessarily the same structure
 - Otherwise complete XML file (or schema) has to be parsed
- Prefix + Unique identifier
 - Prefix is abbreviation for unique identifier
 - Unique identifier is usually a URL
- Used namespaces are declared in document element

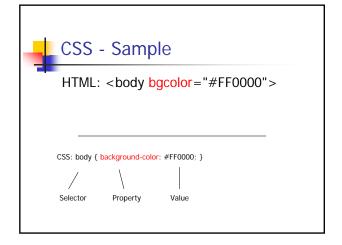

Cascading Style Sheets - CSS

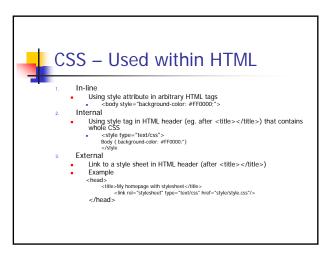

- Allows attachment of style information to HTML
- Modifies Layout of Input elements
- Nesting / Cascading of stylesheets
- External vs. Internal
- May also be applied to XML files!
 - Eg. Automatic rendering of XML files in tabular form (instead of tree)

CSS - Structure

- Generic Structure for StylesSelector { Property: Value }
- Selector specifies class that is modified
- Property denotes a particular property which value is modified

Cascading Style Sheets - CSS

- Allows attachment of style information to HTML
- Modifies Layout of Input elements
- Nesting / Cascading of stylesheets
- External vs. Internal
- May also be applied to XML files!
 - Eg. Automatic rendering of XML files in tabular form (instead of tree)

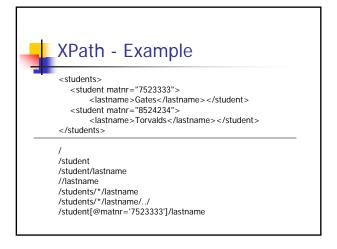

XSL

- eXtended Stylesheet Language
- Consists of
 - XPath (XML Path Language)
 - XSLT (XSL Transformations)
 - XSL-FO XSL Formatting Objects

XPath

- Selection and addressing language
 - for XML (of course)
 - Based on XML's tree structure
- Result of XPath expressions
 - Select single nodes or nodesets (collection of nodes)
- Evaluation always based on local node (context)

XPath - Axes

- Navigation within XML tree with so-called axes
 - child, parent (abbreviation ..), self (.)
 - ancestor, ancestor-or-self (parent)
 - descendant,descendant-or-self (children)
 - following, following-sibling (sequence)
 - preceding, preceding-sibling (sequence)
- Within XPath: [axis-name]::[node-name]
 - /student/child::lastname = /student/lastname
- attributes axis (@)
- namespace axis

XPath – testing with predicates

- Predicate within []
 - evaluated relative to a node expression
- /student/[predicate]/lastname
- Multiple predicates in one expression
 - /student[@matnr='7523333']/name[@nametype='first']
- Attribute testing by value good
- Element testing by value may be difficult
 - because of whitespaces

XPath – Selecting other nodes

- Text Nodes: text()
 - Example: /student[@matnr='7523333']/lastname/text()
- Any node
 - node()
 - /student/* <> /student/node()
 - Difference: node() selects any node, * selects only element nodes

XPath - Expression Types

- Node sets
 - All Node selecting expressions
- Boolean
- Numbers
- Strings
- Result tree fragments
 - Portion of XML document not complete node or node set
 - May be converted to string

XPath – Expressions and Functions

- Functions may be used in predicates
- Node-sets
 - position() returns number of current node in nodeset
 - eg. /student[position() = 2]
 - last() (= last node)
 - count(node-set)
 - eg. count(//students)
 - name(node-set)
 - Name of first node in node set
 - local-name, namespace-uri

- Boolean values
 - Predefined: true & false
 - Results of relational operators (=,!=,<,>,<=,>=)Use &It; instead of <
- Numbers
 - Expressions implicitly converted to a number
 - Arithmetic operators
 - +, -, *, div, mod
 - Functions: floor(), ceiling(), round(), sum()

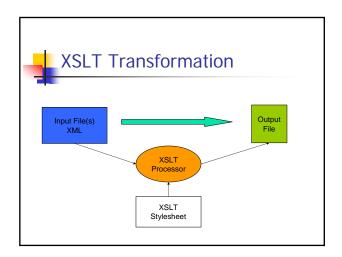

XPath - String

- Functions on string
 - starts-with(s, prefix)
 - contains(s, substring)
 - substring(s, offset, length)
 - normalize-space(s)
 - string-length
 - concat(s1,s2)
 - format-number(number, format-string)
 - **.** ..

XSL Transformations

- Transformation language
 - Written In XML
- Input is XML
- Output may be
 - XML
 - Text
 - HTML
 - Other formats supported via extensions
- Rule based
 - Rules are matched against input

XSLT – Basic principles

- Transformation rule
- <xsl:template match="[XPath-Expression]">
 Substitution-Part
- </xsl:template>

When XPath-Expression evaluates to true for a node the substitution part is applied and allows modification of the tested node.

XSLT - Elements for Substitution

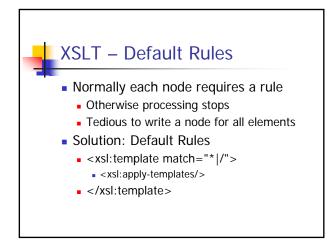

- <xsl:value-of select="xpath-expr">
 - Inserts the text value of an XPath expression into the output
- <xsl:template match="//student"> <xsl:value-of select="lastname"/>
- </xsl:template>

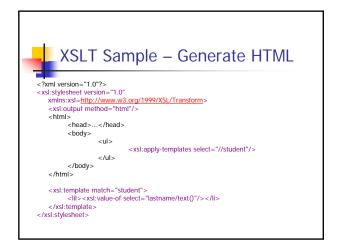

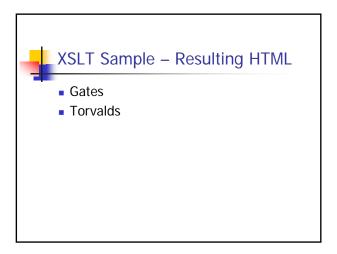

XSLT - Elements for Substitution

- <xsl:apply-templates select="xpath-expr">
 - Specifies where processing shall continue
 - Searches for template rules in select attribute
 - If select omitted processing is done for all elements
- <xsl:text>
 - Outputs normal text
- <xsl:element>, <xsl:attribute>
 - Outputs an element or an attribute
 - Only useful for XML-like output

```
XSLT - Sample
```

XSLT Choices

- <xsl:if test="xpath-expr">
 - Supports conditional processing based on an expression
 - Thee is No else (!)
- <xsl:choose>
 - Like statements switch in Java
 - Single cases in <xsl:when test="xpe"> elements
 - With <xsl:otherwise> else clause possible

XSLT - Iteration / 1

- <xsl:for-each>
 - Iterates over a node-set
- Example
 - <xsl:template match="/">
 - <xsl:for-each select="student">
 - <xsl:value-of select="lastname"/>
 - </xsl:for-each>
 - </xsl:template>
- What's the difference to <xsl:applytemplates>?

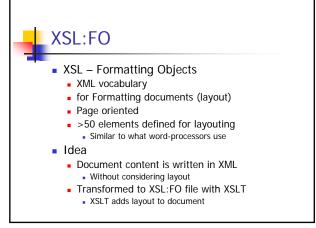

XSLT - Other Features / 1

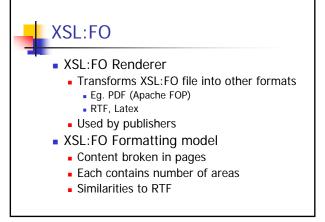

- <variable>
 - Supports declaration of variables that refer to xpath expressions
 - Variables can be reused with \$varname
- <for-each>
 - Supports iteration
 - Over xpath expressions

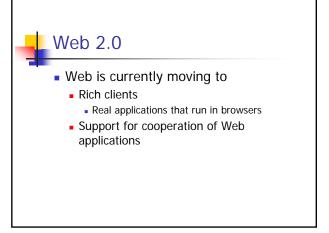

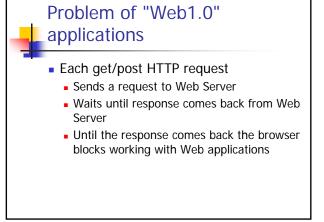

XSLT - Other Features / 2

- <sort>
 - Supports arranging of elements in different order
 As child of <xsl:for-each>, <xsl:apply-templates>
- <number>
 - Inserts formatted integer numbers in output document
- Named templates
 - Parameterized processing
 - Like a subroutine call
 - Recursion is possible and important
- <include>, <import>

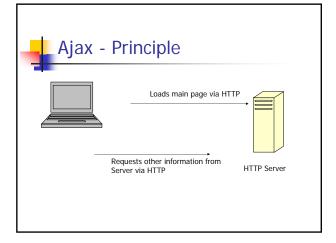

AJAX - Asynchronous JavaScript

- Solves this problem
 - by sending requests in the background
 - Waits for answers in the background
 - Updates the screen asynchronously
 - End users don't have to wait until page is reloaded

AJAX – Key Components

- JavaScript
 - Embedded in HTML pages
 - Executed in the Web browser at the client
 - Supports quicker UI interaction mechanisms in the browser
 - without interaction with the Web server
- DOM Tree
- (X)HTML is modified directly by JavaScript
- CSS
- XMLHttpRequest
 - JavaScript object that supports submitting HTTP Requests asynchronously

Ajax -Working Principle / 1

- JavaScript Startup Code registers JavaScript functions as notification handlers
 - Being called when HTML hyperlinks or HTML form elements are clicked/used
 - Example: Text is entered in a text field
 - Example: Hyperlink is clicked
 - Result: JavaScript handler is invoked when hyperlink clicked, form element is used

Ajax -Working Principle / 2

- JavaScript notification handler is invoked synchronously by browser
 - As in rich GUI applications

 - Uses HTTPXMLRequest object to setup a HTTP request
 Often a Web Service is called via SOAP
 But May just be a request to a Web page
 Registers another Jackcript function as a HTTP response notification handler
 A different function is used(!)
- The HTTP request is sent asynchronously
 - Notification handler for the GUI elements is returned after starting the HTTP request
 - User can continue working in the browser

Ajax -Working Principle / 3

- Some time later the HTTP request is received by the Web Server
 - Sends a response
 - Response comes to the XMLHttpRequest object
 - Processes the response asynchronously
 - Invokes the previously registered Response notification handler

Ajax -Working Principle / 4

- Response notification handler
 - Modifies DOM tree (=XML tree) of the HTML document currently displayed in the browser
 - Supports asynchronous modification of the GUI without stopping the end user in working with the currently displayed window

Web 2.0 / Other developments

- - Really Simple Syndication (RSS 2.0)
 - Rich Site Summary (RSS 0.91, RSS 1.0)
 - RDF Site Summary (RSS 0.9, 1.0)
- - Sharing news

 - Subscription to parts of web pages
 So-called Feeds are sent when web page changes
- XML based
 - RSS 1.0 based on RDF (resource description framework)
 - RSS 2.0 not based on RFD(!)
- Feed readers may be used to read this news

Summary

- XML
 - Ascii of 21st century
- XPath & XSLT
- Web 2.0 Technologies
